I. Influenza-like Illness (ILI) Weekly Summary

- Influenza activity is currently low. This risk assessment is based on:
  - The proportion of emergency department visits for ILI was 1.26%, slightly above the regional baseline of 1.02%, and has been decreasing for four weeks.
  - The proportion of outpatient provider visits for ILI was 0.83%, slightly below the regional baseline of 0.84%, and has been decreasing for four weeks.
  - The proportion of deaths associated with pneumonia or influenza was 6.49%, below the epidemic threshold of 7.36%.
- 188 (11.59%) laboratory specimens tested positive for influenza: 15 influenza A H3N2, 28 influenza A unknown subtype, and 145 influenza B.
- 5 influenza-associated intensive care unit (ICU) hospitalizations were reported during Week 16. 229 ICU hospitalizations have been reported since Week 35 (8/28/16).
- Since Week 35, suburban Cook County has had 0 influenza-associated pediatric deaths, 18 clusters of ILI in schools, and 33 outbreaks of influenza in long-term care facilities.
- **Current recommendations:** Promote respiratory hygiene and prompt treatment with antivirals. Continue to offer vaccination as long as flu viruses are circulating.

Note: Surveillance for ILI in suburban Cook County involves the weekly collection of data from hospitals, physicians' offices, and laboratories. Thank you to all of our surveillance partners for their help in collecting this information.

II. Influenza Activity Level / Disease Burden

The percent of outpatient visits to sentinel providers for ILI is below baseline for the first time since Week 47. Visits to outpatient providers were elevated for 20 consecutive weeks during the 2016-2017 season.
The peak number of influenza-associated hospitalizations for the 2016-2017 season was 32 in Week 8. This number is lower than the peaks of the previous two H3N2 seasons, 2014-2015 and 2012-2013, at 57 and 42, respectively.
Pneumonia and Influenza Mortality

V. Regional Flu Activity
VI. United States Flu Activity

1. Data extracted from syndromic surveillance system, ESSENCE; 45 hospital emergency departments (EDs) participate in ESSENCE. Influenza-like-illness (ILI) defined as a symptom complex of fever and cough or sore throat. ILI = # of ED visits for ILI / total # of ED visits.
2. Data extracted from the U.S. Influenza-like Illness Surveillance Network (ILINet); 6 hospitals and 2 physician offices serve as CDC sentinel sites in Cook County. ILI defined as fever ≥ 100°F, cough and/or sore throat in the absence of a known cause other than influenza. ILI = # of visits for ILI / total # of visits.
3. Includes viral culture, RT-PCR, and the rapid antigen test. Cases may reside outside suburban Cook County. Participating laboratories: Illinois Department of Public Health Sentinel Laboratories, NorthShore University Health System, Loyola University Medical Center, and ACL Laboratories.
4. Includes only suburban Cook County residents (excludes Evanston, Skokie, Oak Park, and Stickney) with known age and residence. Includes all cases reported through the presented week.
5. Includes all deaths where the immediate cause of death or a contributing factor was pneumonia and/or influenza (aspiration pneumonia excluded). Data includes all of Cook County. The 3-week running median is displayed. The percentage of deaths due to P&I are compared with a seasonal baseline and epidemic threshold value calculated for each week. Seasonal baseline is calculated using a periodic regression model that incorporates a CDC based robust regression procedure applied to data from the previous four years. An increase of 1.645 standard deviations above the seasonal baseline of P&I deaths is considered the “epidemic threshold,” i.e., the point at which the observed proportion of deaths attributed to pneumonia or influenza was significantly higher than would be expected at that time of the year in the absence of substantial influenza-related mortality. http://www.cdc.gov/flu/weekly/overview.htm#Mortality
6. Map produced using the proportion of outpatient visits to health care providers for ILI reported through ILINet. Activity levels are compared to the average percent of ILI visits that occur during weeks with little or no influenza virus circulation. http://www.cdc.gov/flu/weekly/index.htm

§Influenza surveillance data are typically aggregated by week. Most years have 52 weeks; however some have 53 weeks. 2014 was a 53-week year. Graphing these years in comparison to 52-week years can be challenging. Because the last week of the calendar year is epidemiologically important for influenza transmission due to holiday family gatherings and school closures, we have graphed these weeks together. In all graphs with 2014-2015 influenza activity represented, Week 53 data appears in the Week 52 column. Consequently, all other data points prior to Week 53 have been moved forward one week, i.e., Week 52 becomes Week 51, Week 51 becomes Week 50, and so on until Week 36 becomes Week 35. This methodology has been adapted from the California Influenza Surveillance Project.
